

# Review of the Pathophysiology of Autism and Possible Benefits of Hyperbaric Oxygen Therapy (HBOT)

Dan Rossignol M.D.  
International Child Development Resource Center  
NR2CON 2007

## HBOT and Autism Overview

At first glance, the use of hyperbaric oxygen therapy (HBOT) in autism appears out of the ordinary. That is what I first thought when I heard about HBOT and autism almost 2 years ago. At the time, no studies existed on the use of HBOT in autistic individuals (there was one published case report [1]). In fact, many people who were proponents for this therapy could not give a theoretical reason why it should/could even work. We began using HBOT in autistic children with a great deal of skepticism. After seeing improvements in some of these children, we decided that further study was needed. Just over 2 years later, we have finished our third study on the use of HBOT in autism. Many of the underlying pathophysiological findings in autism might be ameliorable with HBOT and these have been reviewed in another publication [2]. HBOT in children is generally regarded as safe [3].

## Cerebral Hypoperfusion in Autism

To understand how or why HBOT works in autistic children, we need to review some basic, but newly described, fundamental problems found in many autistic individuals. There are now numerous studies in the medical literature [4-11] demonstrating cerebral hypoperfusion (decreased blood flow in the brain) in as many as 86% of autistic individuals [4]. In one study, this hypoperfusion typically worsened as the age of the autistic child increased, and become “quite profound” in older children compared to younger [5]. Furthermore, this diminished blood flow typically correlates with many core autistic symptoms (see Table 1). When a neurotypical person has to focus on a task or generate speech (in other words, when the brain has to do work), there is an increase in blood flow to the brain, supplying more blood, oxygen, and glucose (fuel) [12]. However, several studies have now demonstrated that not only do some autistic children have diminished blood flow at baseline, they also do not get an increase in blood flow when brain cells have to do more work, such as when the chil-

dren have to focus on a task or generate a sentence [13-15]. In fact, sometimes cerebral blood flow goes *down* and this appears to be mediated, in part, by inappropriate vasoconstriction instead of vasodilatation [15]. The interesting thing about these studies demonstrating cerebral hypoperfusion in autism is that no one has stopped to ask *why* the diminished blood flow exists in the first place. This cerebral hypoperfusion appears to lead to cerebral hypoxia (impaired oxygen delivery) to the brain in some autistic individuals. In fact, several studies have demonstrated a reduction of Bcl-2 and an increase of p53 in the brain of some autistic individuals [80, 81]. Elevated p53 is caused by hypoxia [82] and an increase in Bcl-2 normally protects from cell death provoked by hypoxia; a reduction is associated with increased damage caused by hypoxia [83].

**Table 1: Selected Areas of Cerebral Hypoperfusion in Autism and Clinical Correlations**

<i>Area of Cerebral Hypoperfusion</i>	<i>Clinical Correlation</i>
Thalamus	Repetitive, self-stimulatory, and unusual behaviors [6]
Temporal lobes	Desire for sameness and social/communication impairments [7]
Temporal lobes and amygdala	Impairments in processing facial expressions and emotions [8]
Fusiform gyrus	Difficulty recognizing familiar faces [9]
Wernicke’s and Brodmann’s areas	Decreased language development and auditory processing problems [5; 10]
Temporal and frontal lobes	Decreased IQ [11]

## Cerebral Hypoperfusion and Neuroinflammation in Autism

The cause of cerebral hypoperfusion in autistic individuals is unknown but might be due to inflammation. Evidence published out of Johns Hopkins

in 2005 demonstrates that, upon autopsy, some autistic children present evidence of inflammation in the brain [16]. Also described was inflammation around blood vessels, which is consistent with vasculitis, and could cause the vessel wall to become stiff and inflexible. This in turn might decrease the ability of the blood vessel to dilate and lead to diminished blood flow. There have been several other studies in the literature confirming the presence of inflammation in the brain of autistic individuals [17-19]. Autistic children make more serum autoantibodies to the brain [20], including IgG and IgM autoantibodies to brain epithelial cells and nuclei when compared to typical children [21]. Elevated serum autoantibodies to many neuron-specific antigens and cross-reactive peptides have been found in autistic children [22], including antibodies directed against cerebellar Purkinje cells [23] and neural proteins such as myelin basic protein [22, 24, 25]. Furthermore, 49% of autistic children in one study created serum antibodies against the caudate nucleus and 18% produced serum antibodies to the cerebral cortex [26]. Table 2 summarizes evidence for neuroinflammation in autism.

**Table 2: Evidence of Neuroinflammation in Autism**

<i>A. Elevated markers of neuroinflammation</i>
Activation of microglia and astroglia [16]
Brain IL-6 [16]
Brain MCP-1 [16]
Brian GFAP [18]
CSF GFAP [27]
<i>B. Elevated serum antibodies to brain proteins</i>
Neuron-axon filament protein [28]
GFAP [28]
Brain epithelial cells and nuclei [20; 21]
Myelin basic protein [22; 24]
Myelin associated glycoprotein [22]
Ganglioside [22]
Sulfatide [22]
Chondroitin sulfate [22]
Myelin oligodendrocyte glycoprotein [22]
A,h-crystallin [22]
Neurofilament proteins [22]
Tubulin [22]
Cerebellar Purkinje cells [23]
Caudate nucleus [26]
Cerebral cortex [26]
BDNF [29]

Inflammation generally is associated with edema (increased swelling), can increase the space between cells [30], and might increase the amount of fluid present inside cells. Two fMRI (functional Magnetic Resonance Imaging) studies published in 2006 demonstrated that autistic individuals had more fluid inside brain cells when compared to neurotypical children [31-32]. Furthermore, functional connectivity (the ability of one brain cell to communicate to another) is diminished in some autistic children when compared to neurotypical children [33]. It is possible that inflammation present in the brain of some autistic individuals is leading to diminished blood flow, impaired functional connectivity, and increased fluid inside brain cells as described in these studies.

Furthermore, elevated urinary levels of 8-isoprostane-F2 $\alpha$  have recently been described in some autistic individuals [34]. In some studies, this isoprostane elevation has been shown to cause *in vivo* vasoconstriction and increase the aggregation of platelets. A more recent study on autistic individuals also demonstrated increased urinary levels of isoprostane F2 $\alpha$ -VI (a marker of lipid peroxidation, or oxidative stress), 2,3-dinorthromboxane B2 (which reflects platelet activation), and 6-keto-prostaglandin F1 $\alpha$  (a marker of endothelium activation) [35]. Therefore, the inflammation surrounding blood vessels, and the increase in the inflammatory substances leading to vasoconstriction, and increased activation of platelets and endothelium might cause the diminished cerebral blood flow found in many autistic individuals.

Treatment of this inflammation might help restore normal blood flow. In fact, many inflammatory conditions such as lupus, Kawasaki disease, Behçet's disease, encephalitis, and Sjögren's syndrome are characterized by cerebral hypoperfusion [36-42], and treatment with anti-inflammatory medication can restore normal cerebral blood flow in some of these conditions [43, 44]. In addition, review of the literature demonstrates that the use of anti-inflammatory treatments might improve autistic symptomatology [45]. In fact, treatment with corticosteroids in one child who developed an autoimmune lymphoproliferative syndrome and subsequent autism led to objective improvements in speech and developmental milestones [46]. In another child with PDD-NOS, whose behavior and language regressed at 22 months of age, treatment with corticosteroids ameliorated abnormal behaviors such as hyperactivity, tantrums, impaired social interaction, echolalia, and stereotypies [47].

## Gastrointestinal Inflammation in Autism

Also described in dozens of studies is the presence of inflammation in the intestines of autistic children. This has been termed autistic enterocolitis or chronic ileocolonic lymphoid nodular hyperplasia (LNH). This condition is characterized by mucosal inflammation of the colon, stomach, and small intestine [48-50]. As many as 90% of autistic children with gastrointestinal symptoms (diarrhea, constipation, etc.) have evidence of ileal LNH, with 68% having moderate to severe ileal LNH [48]. Several studies have shown that some autistic children have evidence of inflammatory cells such as lymphocytes [51, 52] and eosinophils [53] inside the gastrointestinal mucosa, sometimes mimicking an autoimmune lesion [51]. Inflammatory markers are also elevated, including TNF- $\alpha$ , Interferon- $\gamma$  (IFN- $\gamma$ ), and IL-6, and anti-inflammatory markers such as IL-10 are decreased [52, 54]. Autistic children typically make significantly more serum antibodies against gliadin and casein peptides resulting in autoimmune reactions [55]. More than 25% of autistic individuals make serum IgG, IgM, and IgA antibodies against gliadin which can then cross-react with cerebellar peptides [23].

## HBOT, Cerebral Hypoperfusion, and Inflammation

Since the cerebral hypoperfusion in autism is likely secondary to inflammation, HBOT might be especially helpful because it possesses potent anti-inflammatory tissue effects [56], with equiva-

lence to diclofenac 20 mg/kg noted in one animal study [57]. HBOT has been used in cases of vasculitis with good results [58], and with some success in disorders characterized by cerebral hypoperfusion including fetal alcohol syndrome [59], cerebral palsy [60, 61], chronic brain injury [62], closed head injury [63], and stroke [64]. HBOT attenuated the production of proinflammatory cytokines including TNF- $\alpha$  [65], IL-1 [65], IL-1 $\beta$  [66], and IL-6 [65], and increased the production of anti-inflammatory IL-10 [67]. HBOT reduced neuroinflammation in a rat model after traumatic brain injury [68]. HBOT diminished both inflammation and pain in an animal model of inflammatory pain [69]. HBOT has been used in humans to achieve remission of Crohn's disease [70-74] and ulcerative colitis [75, 76] not responding to conventional medications, including corticosteroids and immunosuppressive drugs. Interestingly, in some studies, the decrease in inflammation with HBOT appeared to be caused by the increased pressure, not necessarily by the increased oxygen tension. In one animal study, hyperbaric pressure without additional oxygen was shown to decrease TNF- $\alpha$  levels [77]. In a human study, HBOT at 2 atmosphere (atm) and 100% oxygen, and hyperbaric pressure at 2 atm and 10.5% oxygen (thus supplying 21% oxygen, equal to room air oxygen) both showed anti-inflammatory activity by inhibiting IFN- $\gamma$  release, whereas 100% oxygen at room air pressure (1 atm) actually increased IFN- $\gamma$  release [78]. For these reasons, HBOT might help ameliorate the inflammation found in some autistic individuals (see Table 3).

**Table 3: Effects of HBOT on Inflammatory Markers and Inflammation in Autism**

<i>Marker</i>	<i>Classification</i>	<i>Autism Finding</i>	<i>HBOT Effect</i>
TNF- $\alpha$	Inflammatory	↑ [52; 54]	↓ [65; 66; 77 <sup>1</sup> ]
IL-1 $\beta$	Inflammatory	↑ [54]	↓ [66]
IL-6	Inflammatory	↑ [16; 54]	↓ [65]
IL-10	Anti-inflammatory	↓ [52]	↑ [67]
IFN- $\gamma$	Inflammatory	↑ [52]	↓ [78 <sup>2</sup> ]
Neuroinflammation		↑ [16-18]	↓ [65]
GI inflammation		↑ [48-50]	↓ [70; 75]

<sup>1</sup> Hyperbaric pressure without additional oxygen decreased TNF- $\alpha$ .

<sup>2</sup> Hyperbaric pressure without additional oxygen also decreased IFN- $\gamma$ .

## Clinical Studies on HBOT in Autism

In one case report, Heuser et al. treated a four year old child with autism using hyperbaric therapy at 1.3 atm and 24% oxygen and reported “striking improvement in behavior including

memory and cognitive functions” after only ten sessions. The child also had marked improvement of cerebral hypoperfusion as measured by pre-hyperbaric and post-hyperbaric Single Photon Emission Computed Tomography (SPECT) scans [1]. Our previous

case series suggested that hyperbaric therapy at 1.3 atm and 28% oxygen led to clinical improvements in some autistic children as measured by the Autism Treatment Evaluation Checklist (ATEC), Childhood Autism Rating Scale (CARS), and Social Responsiveness Scale (SRS) scales [79]. This low pressure HBOT was well tolerated by all 6 children with no adverse effects noted.

Recently submitted for publication is a prospective open-label study on 18 children with autism who underwent 40 hyperbaric sessions of 45 minutes duration each at either 1.5 atm and 100% oxygen (6 children), or 1.3 atm and 24% oxygen (12 children). Results were calculated before and after the 40 treatments using parent-rated Aberrant Behavior Checklist-Community, SRS, CARS, ATEC, and a Gastrointestinal Scale. Fasting blood was drawn before and after the 40 treatments for C-reactive protein (CRP) and markers of oxidative stress. Results: For the 1.5 atm group, parents reported significant improvements in irritability, lethargy, hyperactivity, motivation, and sensory and cognitive awareness. For the 1.3 atm group, parents reported significant improvements in motivation, mannerisms, physical health, sensory and cognitive awareness, speech, and communication. Mean CRP improved in both groups, especially in a subgroup of children with very elevated initial CRP. There was no statistically significant change in mean plasma oxidized glutathione levels in either group after 40 treatments, although plasma total and free glutathione levels were somewhat diminished. Comparisons between the 2 groups in this study must be done with caution because of the small number of participants involved, but the children receiving the higher pressures (1.5 atm) appeared to have more benefits.

We just finished a prospective, double-blind, controlled study on the use of HBOT at 1.3 atm and 24% oxygen in 61 autistic children. The control group received approximately 1.03 atm (0.5 psi). Parent, psychologists, and physicians evaluated the children and were blinded to the treatment status of the children. We found statistically significant improvements in Clinical Global Impression (CGI) Scales, ATEC, and ABC. This study is currently being prepared for publication.
